1. Introduction to graph | Types | convention used.
2. Graph representation | Two ways
3. What are connected components.
4. BFS (Bredth first search)
5. DFS (Depth first search)
6. Number of Provinces | connected components
7. Number of islands | Number of connected components in graph
8. Flood Fill Algorithm
9. Rotten oranges
10. Detect cycle in an undirected graph using BFS
11. Detect cycle in an undirected graph using DFS
12. Distance of nearest cell having 1 0/1 matrix.
13. Surrounded Regions | Replace O's with X's.
14. Number of enclaves | Multisourc BFS.
15. Number of distinct island | constructive thinking + DFS
16. Bipertite Graph | BFS
17. Bipertite Graph | DFS
18. Detect cycle in a directed graph using DFS
19. Find Eventual safe states - DFS
20. Topological sort Algorithm | DFS
21. Kahn's Algorithm | Topological sort Algorithm | BFS
22. Detect a cycle in a directed graph | Topological sort | Kahn's Algorithm | BFS
23. Course schedule I and II | Pre-requisite Task | Topological sort
24. Find Eventual safe states | BFS | Topological sort
25. Alien Dictionary | Topological sort
26. Shortest path in Directed Acyclic graph Topological sort.
27. Shortest path in undirected graph with unit weights
28. Word Ladder - I | Shortest paths
29. Word Ladder - II | Shortest paths
30. Dijkstra's Algorithm - using priority queue
31. Dijkstra's Algorithm - using set
32. Dijkstra's Algorithm why Pq and not Q, intuition Time complexity Analysis
33. Print shortest path - Dijkstra's Algo
34. Shortest distance in a Binary maze.
35. Path with minimum Effort
36. cheapest flight with k stops
37. Minimum multiplication to reach End
38. No. of ways to arrive at destination
39. Bellman Ford Algorithm
40. Floyd warshall Algorithm
41. Find the city with smallest no. of neighbours at a threshold distance
42. Minimum spanning Tree - Theory
43. Prim's Algorithm - minimum spanning Tree
44. Disjoint set | union by rank | union by size | path compression
45. Kruskal's Algorithm - minimum spanning Tree
46. Number of provinces - Disjoint set
47. Number of operations to make Network connected | DSU
48. Accounts Merge | DSU
49. Number of Island - II - Online queries - DSU
50. Making a large island - DSU
51. Most stones Removed with same row or column - DSU
52. Strongly connected components - Kosaraju's Algorithm
53. Bridges in graph - using Tarjan's Algorithm of time in and low time
54. Articulation point in graph

Lec 1

IN GRAPH

01-/04/2023

There are two types of graph
(1) undirected graph & (11) Directed graph

cycle in a graph

This is also graph

Defn: Start from a node and end at that node is called cycle.

cyclic graph

Directed Acyclic graph (DAG)

Path: Contain a lot of nodes and each of them are reachable.

1 2 3 5 — path

1 2 ~~3~~ 2 1 — Not a path

A node can't appear twice in a path.

1 3 5 ✗ Not a path

@Ashish Kumar Nayak

Degrees on Graph :-

D(3) → 3 for an ~~un~~

D(4) → 2

D(5) → 3

D(2) → 2

D(1) → 2

for an undirected graph the no. of edges that are attached to it is called degree.

$$\boxed{\text{Total Degree of a graph} = 2 \times \text{no. of edges}}$$

for directed graph :-

Indegree(node)

Outdegree(node)

Indegree(3) = 2

Outdegree(3) = 1

edge weights :-

if weight is not assign unit weight

@Aashish Kumar Nayak

Lec 2

Lec

input

n-nodes , m- edges
5 6

m lines
↓
Represent edges

2	1
1	3
2	4
3	4
2	5
4	5

5 6

m lines

1	3
2	1
2	4
3	4
2	5
4	5

Two way for store

(1) Matrix (2) List

1	2
1	3
2	4
3	4
3	5
4	5

(1) matrix

	0	1	2	3	4	5
0	0	0	0	0	0	0
1	0	0	1	1	0	0
2	0	1	0	0	1	0
3	0	1	0	0	1	0
4	0	0	1	1	0	1
5	0	0	0	1	1	0

Space costly $n \times n$

@Aashish Kumar Nayak

Code :

```
int main()
{ int n, m;
  cin>>n>>m;
  int adj[n+1][m+1];
  for( int i=0; i<m; i++)
   { int u,v;
     cin>> u>>v;
     adj[u][v] = 1;
     adj[v][u] = 1;
   }
  return 0;
}
```

(ii) List :

1 → {2, 3}
2 → {1, 4, 5}
3 → {1, 4}
4 → {2, 3, 5}
5 → {2, 4}

Code :

```
int main()
{ int n, m;
  cin >>n>>m;
  ~~int adj~~ vector<int> adj[n+1];
  for(int i=0; i<m; i++)
   { int u,v;
     cin>>u>>v;
     adj[u].push_back(v);
     adj[v]. push_back(u);
   }
  return 0;
```

for directed graph

adj[u]. push_back(v);

S.C. : O(Edges)

@Aashish Kumar Nayak

weighted graph :-

Matrix

	0	1	2	3
0				
1			2	
2		2		
3				

adj[v][v] = weight.

list

0 we will store pair.

1

2

3

4 → { 2, 3, 5 } → instead of this store this

5

{ (2,1), (3,4), (5,3) }
weight

3. Lec 4.

Connected components :-

N = 10, M = 8

1 2
1 3
2 4
3 4
5 6
6 7

4 different components of a single graph

it can be also 4 different graph.

But according to input / question it is a single graph.

@Aashish kumar Nayak

vis [| | | | | |]

if we start from 1st component then we will never reach to the 2nd component so for that we will use something like visited array.

vis [| | | | | | | | | |] N=11
0 1 2 ... 10

```
for (i = 1 → 10)
    if(!vis[i])
        traversal(i);
```

for any traversal if node is not visited. // then call traversal also from this node.

A. Lec 5.

BFS (Breadth First Search)

level
0
1
2
3

Breadth → levelwise

1 | 2 6 | 3 4 7 8 5 ...
0 | 1 | 2 | 3

let say 6 is starting node

6 | 1 7 8 | 2 5 | 3 4
0 | 1 | 2 | 3

@Aashish Kumar Nayak

It is same ~~to~~ like level order traversal

0 — { }
1 — {2, 6}
2 — {1, 3, 4}
3 — {2}
4 — {2, 5}
5 — {4, 8}
6 — {1, 7, 9}
7 —

vis

0	1	2	3	4	5	6	7	8	9
0	1	1	1	1	1	1	1	1	1

output: 1 | 2 6 | 3 4 7 9 | 5 8

0 | 1 | 2 | 3

Code :-

```
vector<int> bfsOfGraph(int V, vector<int> adj[])
{   int vis[n] = {0};
    vis[0] = 1;
    queue<int> q;
    q.push(0);
    vector<int> bfs;
    while(!q.empty())
    {   int node = q.front();
        q.pop();
        ~~bfs.push_back~~
        bfs.push_back(node);

        for(auto it : adj[node])
        {   if(!vis[it])
            {   vis[it] = 1;
                q.push(it);
            }
        }
    }
    return bfs;
}
```

$O(N) \times O(2E)$

~~N+(2E)~~ $1 + (2E)$

S.C. — $O(3N) \simeq O(N)$

T.C. — $O(N) + O(2E)$

2E = Total degree

T.C. — $\underset{1}{O(N)} + \underset{3}{O(2E)}$ (degree)

run for degree of node

@Aashish Kumar Nayak

5: Lec 6

DFS (Depth First Search) : Recursion

Starting node = 1

we can choose any path

1 2 5 6 3 7 8 4

Main thing is, ~~traversing~~ in depth

if Starting node = 3

3 4 8 7 1 2 5 6

Recursion is an algo which goes till depth calculate and returns back.

So we use recursion in DFS.

vis

Adjacency list :

1 - {2,3}
2 - {1,5,6}
3 - {1,4,7}
4 - {3,8}
5 - {2}
6 - {2}
7 - {3,8}
8 - {4,7}

@Aashish Kumar Nayak

```
vector<int> dfsOfGraph(int V, vector<int> adj[])
{
    int vis[V] = {0};
    int start = 0;
    vector<int> ls;
    dfs(start, adj, vis, ls);
    return ls;
}

void dfs(int node, vector<int> adj[], int vis[], vector<int> &ls)
{
    vis[node] = 1;
    ls.push_back(node);
    for(auto it : adj[node])
    {
        if(!vis[it])
        {
            dfs(it, adj, vis, ls);
        }
    }
}
```

S.C. → $\underset{dfs}{O(N)} + \underset{visited}{O(N)} + \underset{Recursion}{O(N)}$

$\approx O(N)$

T.C. → $O(N) + \underset{degree}{O(2E)}$

↓ For directed graph

T.C. → $O(E)$

Lec 7. Q: Number of Provinces :-

1 — 2
2 — 1, 3
3 — 2
4 — 5
5 — 4, 6
6 — 5
7 — 8
8 — 7

No. of provinces = 3

From node 1 we can go 2, 3 or, from ② → 1, 3, from ③ → ①, ② so ① — ② this is 1 province.
③

@Aashish Kumar Nayak

we will have multiple starting point

start = 1/2/3
start = 4/5/6
start = 7/8

~~Class~~

```
void dfs(int node, vector<int> adjLs[], int vis[])
{
    vis[node] = 1;
    for(auto it : adjLs[node])
    {
        if(!vis[it])
        {
            dfs(it, adjLs, vis);
        }
    }
}
```

T.C. $O(N) + O(V+2E)$ — for all dfs node
$\approx O(N)$

S.C. — $O(N) + O(N)$ — Recursion stack space

```
int numProvinces(vector<vector<int>> adj, int v)
{
    vector<int> adjLs[v];
    for(int i=0; i<v; i++)
    {
        for(int j=0; j<v; j++)
        {
            if(adj[i][j] == 1 && i != j)
            {
                adjLs[i].push_back(j);
                adjLs[j].push_back(i);
            }
        }
    }
    int vis[v] = {0};
    int cnt = 0;
    for(int i=0; i<v; i++)
    {
        if(!vis[i])
        {
            cnt++;
            dfs(i, adjLs, vis);
        }
    }
    return cnt;
}
```

1 — 2
2 — 1,3
3 — 2

@Ashish Kumar Nayak

~~No. of component~~

Number of Islands

@Aashish Kumar Nayak

	0	1	2	3
0	0	1	1	0
1	0	1	1	0
2	0	0	1	0
3	0	0	0	0
4	1	1	0	1

no. of Island
3 starting Nodes
8 Island

Using BFS

Starting — {0,1}

Visited array

	0	1	2	3
0		✓	✓	
1		✓	✓	
2			✓	
3				
4				

~~{0,2}~~

~~{2,3}~~
~~{1,3}~~
~~{1,2,3}~~
~~{0,2}~~
~~{0,1}~~

{0,1} φ

adjacency list

They can be neighbour
so we will go in all
8-direction.

Then after traversal the queue will be empty

Now starting point will change and process will be same.

so we will use three starting points.

for finding starting points we will traverse from (0,0) to (n-1, n-1) and if we find 0 then ignor while

if we find, then call traversal also.

pseudo code :-

```
for(row -> (0-n))
{
    for (col -> (0-m))
    { if(!vis[row][col]
        {
            bfs(row, col);
            cnt++;
        }
    }
}
```

for BFS traversal

we have to visit all the neighbour nodes.

for that we can write a code

```
for(delrow -1 to 1)
{ for(delcol -1 to 1)
    {new_row = row + delrow;
     new_col = col + delcol;
    }
}
```

©Aashish Kumar Nayak

```
void bfs( int row, int col, vector<vector<int>> &vis,
vector<vector<char>> &grid)
{
        vis[row][col] = 1;
        queue<pair<int,int>> q;
        q.push({row, col}); int n = grid.size();
        while(!q.empty()) int m = grid[0].size();
        {
                int row = q.front().first;
                int col = q.front().second;
                q.pop();
        // traverse in the neighbours & mark them visited

        for( int delrow = -1; delrow <= 1 ; delrow++)
                {
                for(int delcol = -1; delcol <= 1; delcol ++)
                        {
                        int nrow = row + delrow;
                        int ncol = col + delcol;
                        if(nrow >= 0 && nrow < n &&
ncol >= 0 && ncol < m && grid[nrow][ncol] == '1' &&
!vis[nrow][ncol])
                        {
                        vis[nrow][ncol] = 1;
                        q.push({nrow, ncol});
                        }
                }
        }
}
```

@Aashish Kumar Nayak

```
int numIslands(vector<vector<char>> &grid)
{
    int n = grid.size();
    int m = grid[0].size;
    vector<vector<int>> vis(n, vector<int>(m,0));
    int cnt = 0;
    for(int row=0; row<n; row++)
    {
        for(int col=0; col<m; col++)
        {
            if(!vis[row][col] && grid[row][col] == '1')
            {
                cnt++;
                bfs(row, col, vis, grid);
            }
        }
    }
    return cnt;
}
```

S.C. :- $O(N^2) + O(N^2)$
matrix queue
$\approx O(N^2)$

T.C :- $N^2 + N^2 \times 9$
matrix check for 1 BFS

$\approx O(N^2)$

In matrix use BFS

@Aashish Kumar Nayak

Lec 9

Flood Fill Algorithm

Ex

By DFS

sr, sc — starting coordinate. DFS(2,0)

initial = 2

new color = 3

	0	1	2
0	1	1	1
1	2	2	0
2	2	2	0

DFS(1,0)

DFS(2,1)

DFS(1,1)

DFS(2,1)

we can choose BFS / DFS any of them

But we choose DFS here for no reason

initial color will be image[sr][sc]

Code:

```
vector<vector<int>> floodFill (vector<vector<int>> &image,
int sr, int sc, int newcolor)

{ int inicolor = image[sr][sc];   //2
    vector<vector<int>> ans = image;
    int delRow[] = {-1, 0, +1, 0};
    int delCol[] = {0, 1, 0, -1};
    dfs(sr, sc, ans, image, newcolor, delRow, delCol, inicolor)
    return ans;
}
```

@Aashish Kumar Nayak

```
void dfs(int row, int col, vector<vector<int>> &ans, vec
vector<vector<int>> &image, int delrow[], int delcol[])
{
    ans[row][col] = newColor;
    int n = image.size();  int m = image[0].size();
    for(int i = 0; i<4; i++)
    {
        int nrow = row + delrow[i];
        int ncol = col + delcol[i];
        if(nrow >= 0 && nrow < n && ncol >= 0 &&
        nrow < m && image[nrow][ncol]
        == iniColor && ans[nrow][ncol] != newcolor)
        {
            dfs(nrow, ncol, ans, image, newcolor, delrow,
            delcol);
        }
    }
}
```

T.C. $(N \times M) \times 4$ — matrix for every 4 neighbour node

$= (N \times M) + (N \times M) \times 4$ — call dfs, dfs

$\approx O(N \times M)$

S.C. $O(N \times M) + delrow + delcol$

$\approx O(N \times M)$

@Aashish Kumar Nayak

Rotten oranges :-

we have to ~~find~~ the minimum time to rotten all the oranges.

0	1	2
0	1	1
2	1	1

0 — Empty box
1 — Fresh orange
2 — rotten orange

* in 1 unit of time if it can rott ← ↑ ↓ → 4 oranges if avilable.

* if you can't rotten all orages than return -1.

Sol

we have to visit same level nodes at same time & BFS is the only traversal algo which traverse Level wise

if we use DFS

0	2	2
0	2	2
2	2	2

it will take 5 sec

But we have to do it in min time and that is only possible if we move in the neighbouring direction with equal Peace.

BFS simultaneously rotten.

BFS

	0	1	2
0	0	1	2
1	0	1	1
2	2	1	1

with time +1

(2,0) t = 0

(0,2) t = 0

with time +1

(2,1) t = 1

Queue (q)

(2,2), 2
~~(1,1), 2~~
(0,1), 1
~~(1,2), 1~~
(2,1), 1 ← time
~~(0,2), 0~~ rotten
~~(2,0), 0~~

max time = ~~0~~ 1 2

visited

	0	1	2
0	0	2	2
1	0	2	2
2	0	2	2

Max time = 2 sec

return max time,

(r-1, c)
(r, c-1) ← (r, c) → (r, c+1)
(r+1, c)
neighbour nodes

@Aashish Kumar Nayak

```
int orangesrotting(vector<vector<int>> &grid)
{
    int n = grid.size();
    int m = grid[0].size();

    queue< pair< pair<int,int>, int>> q;
    int vis[n][m];
    int cntfresh = 0;
    for(int i=0; i<n; i++)
    {
        for(int j=0; j<m; j++)
        {
            if(grid[i][j] == 2)
            {
                q.push({{i, j}, 0});
                vis[i][j] = 2;
            }
            else {
                vis[i][j] = 0;
            if( grid[i][j] == 1)
                { cntfresh ++;
                }
            }
        }
    }
    int tm = 0;
    int drow[] = {-1, 0, +1, 0};
    int dcol[] = {0, 1, 0, -1};
    int cnt = 0;
    while(!q.empty())
    {
        int r = q.front().first.first;
        int c = q.front().first.second;
        int t = q.front().second;
        tm = max(tm, t);
        q.pop();
        for(int i=0; i<4; i++)
        {
            int nrow = r + drow[i];
            int ncol = c + dcol[i];
            if(nrow >=0 && nrow<n && ncol>=0 && ncol<m && vis[nrow][ncol]==0
            && grid[nrow][ncol] == 1) { q.push({{nrow, ncol}, t+1});
                vis[nrow][ncol] = 2; cnt++; }}}
```

time

T.C. $O(N \times M)_{vis} + O(N \times M)_{oranges}$

$\approx O(N \times M)$

T.C. $O(N \times M)_{loop} + O(N \times M) \times 4$

every node, neighbour

$\approx O(N \times M)$

@ Aashish Kumar Nayak

```
if(cnt != cntFresh)
    return -1;

return tm;
}
```

Detect a cycle in an undirected graph :-

Using BFS

if you are starting traverse and you are able to come back at that particular node then there will be cycle in the graph.

adj list

1 - {2, 3}
2 - {1, 5}
3 - {1, 4, 6}
4 - {3}
5 - {2, 7}
6 - {3, 7}
7 - {5, 6}

we are at level 2 ⇒ 5, 6 and from both side if we touched 7 it means there is a cycle

~~(6,3)~~
~~(4,3)~~
~~(5,2)~~
~~(3,1)~~
~~(2,1)~~
~~(1,-1)~~

q

vis

1	2	3	4	5	6	7
1	1	1	1	1	1	1

for component graph

```
for( i = 1; i<=n; i++)
{   if( !vis[i] )
    {   if( detectCycle(i) == true)
            return true;
    }
}
return false;
```

Component thing

T.C. - $O(N + 2E) + O(N)$

S.C. - $O(N) + O(N)$
queue visited

$\approx O(N)$

@Aashish Kumar Nayak

```
bool detect(int src, vector<int> adj[], int vis[])
{
    vis[src] = 1;
    queue<pair<int,int>> q;
    q.push({src, -1});
    while(!q.empty())
    {
        int node = q.front().first;
        int parent = q.front().second;
        q.pop();

        }
    }
    return false;
}
```

Node parent

@Aashish Kumar Nayak

Cycle detection in undirected graph → using DFS

Start from somewhere and if we got a node which is previously visited, then we can there is cycle.

and it should ~~different~~ not be parent of that node.

Adj List

1 - 2,3
2 - 1,5
3 - 1,4,6
4 - 3
5 - 2,7
6 - 3,7
7 - 5,6

vis

1	2	3	4	5	6	7
1	1	1	1	1	1	1

normal node, parent node

DFS(1, -1)

T

DFS(2, 1)

no need for further call

because we got True

DFS(3, 1)

we will go this call after completing the DFS(2,1) call

DFS(1, already visited but parent is same as node so, it is not cycle.

DFS(5, 2)

T

DFS(7, 5)

T

DFS(6, 7)

for 7 there will be no call because it is parent

DFS(3, 6)

T

DFS(4, 3)

DFS(1, 3)

return true,

3 is marked visited and also it is not parent, so we got the cycle.

∴ return true.

@Aashish Kumar Nayak

```
bool dfs(int node, int parent, vector<int>&vis[], vector<int>
  adj[])
{ vis[node] = 1;
    for (auto adjacentNode : adj[Node])
    {
      if(!vis[adjacentNode])
      {
        if(dfs(adjacentNode, Node, vis, adj) == true)
          return true;
      }
      else if (adjacentNode != parent)
      { return true; }
    }
    return false;
}
```

```
bool isCyclic(int v, vector<int> adj[])
{ int vis[v]={0};
  for (int i=0; i<v; i++)
  { if(!vis[i])
      {
        if( dfs(i, -1, vis, adj ==true)
        {
          return true;
        }
      }

  return false;
}
```

S.C. – O(N) + O(N) ≈ O(N)
(Recursion, Vis)

T.C. – DFS Traversal
O(N + 2E) + O(N)
≈ O(N + 2E) for loop

Not O(N) — But it will depend on components
e.g. 1 & 3 O(3)

@Aashish Kumar Nayak

Distance of nearest cell having 1 :

for this one itself

1	0	1
1	1	0
1	0	0

× no diagonal distance

$$\begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 2 \end{bmatrix}$$

return Ans

∵ This is something related to graph, and also we have to ~~min~~ find min steps or min distance, it means it is a graph problem.

which algo – BFS comes in my mind.

Because it will simultaneously travels in all direction and always minimum count.

}}
}  return dist;
```

@Ashish Kumar Nayak

Replace O's with X's

X	X	X	X
X	O	X	X
X	O	O	X
X	O	X	X
X	X	O	O

only those ~~ze~~ O's which are surrounded by X in top, down, left, right that can be converted into X. rest ~~are~~ will not converted.

Observation : ~~if someone is on the boundary they~~ Can A set of X connected to a boundary 'O' cannot be converted.

DFS

① go to the boundary and bind if there is zero if we got zero ~~cw~~ then call the dfs ~~for~~ from that index

	0	1	2	3	4
0	X	X	X	X	X
1	X	O	O	X	O
2	X	X	O	X	O
3	X	O	X	O	X
4	O	O	X	X	X

VIS

O	O	O	O	O
O	X	X	O	1
O	O	X	O	1
O	1	O	X	O
1	1	O	O	O

dfs(4,0)

dfs(4,1)

dfs(3,1)

X

It is already mark no need to travel again

dfs(1,4)

dfs(2,4)

X

Some visited from Boundary so can't convert.

@Aashish Kumar Nayak

Algo:-

→ from boundary, find '0's & traverse & mall all 0's connected to it.

then → Rest of zero can be converted into X.

Code:-

```
void dfs(int row, int col, vector<vector<int>> &vis, ~~vector<~~
vector<vector<char>> &mat, int delrow[], int delcol[])
{ vis[row][col] = 1;
  int n = mat.size();
  ~~int m = mat.size();~~ int m = mat[0].size;
  for( int i = 0; i<4; i++)
    { int nrow = row + delrow[i];
      int ncol = col + delcol[i];
    if(nrow >=0 && nrow <n && ncol >=0 && ncol < m
    && !vis[nrow][ncol] && mat[nrow][ncol] == '0')
    {  dfs(nrow, ncol, vis, mat, delrow, delcol);
    }
  }
}

vector<vector<char>> fill( int n, int m, vector<vector<char>> mat)
{ int delrow = {-1, 0, 1, 0};
  int delcol = {0, 1, 0, -1};
  vector<vector<int>> vis(n, vector<int>(m,0));
  ~~for~~ //traverse first & last row,
  for(int j=0; j<m; j++)
    { if(! vis[0][j] && mat[0][j] == '0')
      { dfs(0, j, vis, mat, delrow, delcol);
      }
      if(! vis[n-1][j] && mat[n-1][j] == '0')
       { dfs(n-1, j, vis, mat, delrow, delcol);
       }
    }
  ~~for(int~~ // ~~traver~~

  //traverse for 1st col & last col
```

@Aashish Kumar Nayak

```
for(int i=0; i<n; i++)
{
    if(!vis[i][0] && mat[i][0] == '0')
    {
        dfs(i, 0, vis, mat, delrow, delcol);
    }

    if(!vis[i][m-1] && mat[i][m-1] == '0')
    {
        dfs(i, m-1, vis, mat, delrow, delcol);
    }
}

for(int i=0; i<n; i++)
{

@Aashish Kumar Nayak

Number of Enclaves | Multi-source BFS

count the no. of 1's or land from where you can not go outside the matrix. (inside 1's)

(B means B you can't count 1's which is on boundary and also the 1's which is connected to the boundary 1's)

so then the remaining 1's will be our answer.

lets try BFS for no reason just to get clarity

	0	1	2	3	4
0	0	0	0	1	1
1	0	0	1	1	0
2	0	1	0	0	0
3	0	1	1	0	0
4	0	0	0	1	1

put all boundary's 1

~~1,2~~
~~0,4~~
~~1,3~~
~~4,4~~
~~4,3~~
~~0,4~~
~~0,3~~

Vis

0	0	0	1	1
0	0	1	1	0
0	0	0	0	0
0	0	0	0	0
0	0	0	1	1

← b →
↓

Once the queue is empty
now count the unvisited 1's and return this ans.

~~ans~~ ans = 3

@Aashish Kumar Nayak

Code :-

@Aashish Kumar Nayak

```
int numberofEnclaves(vector<vector<int>> &grid)
{ queue<pair<int,int>> q;
    int n = grid.size();
    int m = grid.size();
    int vis[n][m] = {0};
    for(int i=0; i<n; i++)
      { for(int j=0; j<m; j++)
        { if(i==0 || j==0 || i=n-1 || j==m-1)
          { if(grid[i][j] == 1)
            { q.push({i,j});
              vis[i][j] = 1;
            }
          }
        }
      }
    int delrow[] = {-1, 0, +1, 0};
    int delcol[] = {0, +1, +0, -1};
    while(!q.empty())
      { int row = q.front().first;
        int col = q.front().second;
        q.pop();
        for(int i=0; i<4; i++)
          { int nrow = row + delrow[i];
            int ncol = col + delcol[i];
            if(nrow >=0 && nrow <n && ncol >=0 && ncol<m &&
              vis[nrow][ncol] == 0 && grid[nrow][ncol] == 1)
              { q.push({nrow, ncol});
                vis[nrow][ncol] = 1;
              }
          }
      }
    int cnt=0;
    for(int i=0; i<n; i++)
      { for(int j=0; j<m; j++)
        { if(grid[i][j] == 1 & vis[i][j] == 0) cnt++;
        }
      }
return cnt;}
```

$\approx O(N \times M)$

S.C. - $\approx O(N \times M)$

Number of distinct Islands

@Ashish Kumar Mayak

These are identicle so it will be count as 1.

There is 8 distinct island.

1 way is we can store the shapes in a set so that it will store only unique shapes.

How to store these shapes ~~so that~~ ~~we~~ such that these two come out to be identical

{(0,0) (0,1) (1,0)}
{(2,3) (2,4) (3,3)} } These are not identicle

so make starting point as base origin

(0,0) − (0,0) = (0,0)
(0,1) − (0,0) = (0,1)
(1,0) − (0,0) = (1,0)

= {(0,0) (0,1) (1,0)}

(2,3) − (2,3) = (0,0)
(2,4) − (2,3) = (0,1)
(3,3) − (2,3) = (1,0)

= {(0,0) (0,1) (1,0)}

} Now these are identicle

(0,3) − (0,3) = (0,0)
(0,4) − (0,3) = (0,1)
(3,0) − (3,0) = (0,0)
(3,1) − (3,0) = (0,1)

{(0,0) (0,1)}
{(0,0) (0,1)} } T

but what if

1 1 1 1

1 1 1

1

so must follow the same order for all shapes.

1 1 0

1 0 0

Code :-

```
int countDistinctIslands( vector<vector<int>> & grid )
{ int n = grid.size();
  int m = grid[0].size();
  vector<vector<int>> vis(n, vector<int>(m, 0));
  set<vector<pair<int, int>>> st;
  for(int i=0; i<n; i++)
  {
    for(int j=0; j<m; j++)
    {
      if(!vis[i][j] && grid == 1)
      {
        vector<pair<int, int>> vec;
        dfs(i, j, vis, grid, vec, i, j);
        st.insert(vec);
      }
    }
  }
  return st.size();
}
```

@Ashish Kumar Nayak

```
void dfs(int row, int col, vector<vector<int>> & vis,
vector<vector<int>> &grid, vector<pair<int,int>> &vec, int
row0, int col0)
{
    vis[row][col] = 1; ~~vec.push_back({row-row0, col-col0});~~
    int n = grid.size();
    int m = grid[0].size();
    vec.push_back({row-row0, col-col0});
    int delrow[] = {-1, 0, 1, 0};
    int delcol[] = {0, -1, 0, 1};
    for(int i=0; i<4; i++)
    {
        int nrow = row + delrow;
        int ncol = col + delcol;
        if(nrow >=0 && nrow < n && ncol >=0 && ncol < m
        && !vis[nrow][ncol] && grid[nrow][ncol] == 1)
        {
            dfs(nrow, ncol, vis, grid, vec, row0, col0);
        }
    }
}
```

for loop dfs × neighbour

T.C. $\cancel{O(N\times M)} + O(N\times M)\times 4$

Bipartite graph

@Aashish Kumar Nayak

Colour the graph with 2 colours such that no adjacent nodes have same colour.

Hence this is not a Bipartite graph.

We can't colour this node with any of the two colours

* Linear graphs with no cycles are always Bipartite graph.

* Any graph with even ~~cycle~~ length cycle can also be Bipartite.
* Any graph with odd length cycle can never be a Bipartite.

We will solve this problem using BFS

& instead of visited array we will take colour array.

adj. list

1 - {2, 7}
2 - {3, 6}
3 - {2, 4}
4 - {2, 5, 7}
5 - {4, 6}
6 - {2, 5}
7 - {4, 8}
8 - {7}

colour

0	1	2	3	4	5	6	7	8
0	1	-1	-1	-1	-1	-1	-1	-1

node = 4

code :

```
bool cheak( int start , int v , ~~vector<int>~~
vector<int> adj[] , int color[])
  { queue <int> q;
    q.push (start);
      color[start] = 0;
  while ( !q.empty ())
    {  int node = q.front();
       q.pop();
       for (auto it : adj[node])
         {  if( color [it] == -1)
              { color[it] = !color [node];
                q.push (it);
              }
            else if( color [it] == color [node])
              { return false;
              }
         }
    }
       return true;
  }

         { return false; }
   }
   return true;
}
```

@Aashish Kumar Nayak

Detect cycle in a directed graph

visited algorithm using the DFS will not work here
this ~~with~~ algo will work only in undirected graph

for ex:-

dfs(1)
↓
dfs(2)
↓
dfs(3) → dfs(7)
↓
dfs(4)
↓
dfs(5)

According to visited algo using DFS

This is a cycle but this is not true.

So [on the same path, node has to be visited again]

	0	1	2	3	4	5	6	7	8	9	10
vis —	0	1	1	1	1	1	1	1	1	1	1
path vis —		0	0	0	0	0	0	0	1	1	1

dfs(1)
↑
dfs(2)
↑
dfs(3) → dfs(7)
↑
dfs(4)
↑
dfs(5)
↑
dfs(6)
↓
false

when we are returning then make path unvisited visited array.

dfs(8)
↓
dfs(9)
↓
dfs(10)
↓
we dfs(8)

T ↑ T ↑ T ↑

1 – 2
2 – 3
3 – 4, 7
4 – 5
5 – 6
6 –
7 – 5
8 – 2, 7
9 – 10
10 – 8

we got 8 which is visited & path visited
return true.

@Aashish Kumar Nayak

Code :-

```
bool dfscheak(int node, vector<int> adj[], int vis[], int
pathvis[])
{   vis[node] = 1;
    pathvis[node] = 1;
    for(auto it : adj[node])
      {  if(!vis[it])
           {  if(dfscheak(it, adj, vis, pathvis) == true)
                return true;
           }
         else if (pathvis[it])
           {  return true;
           }
      }
    pathvis[node] = 0;
    return false;
}
bool iscyclic(int v, vector<int> adj[])
{   int vis[v] = {0};
    int pathvis[v] = {0};
    for(int i=0; i<v; i++)
    {   if(!vis[i])
          {  if(dfscheak(i, adj, vis, pathvis) == true)
               return true;
          }
    }
    return false;
}
```

T.C. - $O(V+E)$

S.C. - $O(2N)$
$\approx O(N)$

@Aashish Kumar Nayak

Find Eventual safe states :-

we have to find which are the safe node ->

terminal nodes

↳ outdegree ⇒ 0

Nodes which are ending at terminal node

Safe Node arr → [2, 4, 5, 6]

→ Any one who is a part of cycle can not be safe node

→ Any one that leads to a cycle can not be safe node

→ Rest of all are safe nodes

we will solve by cycle detection technique.

@ Ashish Kumar Nayak

Code:

```
bool dfscheak( int node, vector<int> adj[] ,int vis[],
int pathvis[], int cheak[])
{

T.C. - $O(V+E)$

directed graph

@Aashish Kumar Nayak

Kahn's Algorithm (Topological sort) :-

we will use queue & indegree array

indegree

0	1	2	3	4	5
~~2~~ 1	~~2~~ 1	~~1~~ 0	~~0~~ 1	0	0

There is no element which comes to 4 & 5 indegree = 0

so we can place 4, 5 in starting

Step 1 :- Insert all nodes with indegree 0

Step 2 :- take them out of the queue.

Step 3 :- Remove the degree of adjacent nodes.

How we find indegree

we can do that from adj list.

2 → 3 it means indegree of 3 is 1

so we will increase ++ indegree.

0 → { }
1 → { }
2 → {3}
3 → {1}
4 → {0,1}
5 → {0,2}

© Aashish Kumar Nayak

Code :-

```
vector<int> toposort(int v, vector<int> adj[])
{ int degree[v] = {0};
  for(int i = 0; i<v; i++)
  {
    for(auto it: adj[i])
    {
      indegree[it]++;
    }
  }

  queue<int> q;
  for(int i=0; i<v; i++)
    {if( indegree[i] == 0)
      { q.push(i);
      }
    }
  vector<int> topo;
  while(!q.empty())
  {
    int node = q.front();
    q.pop();
    topo.push_back(node);

  for(auto it: adj[node])
    { indegree[it]--;
      if(indegree[it] == 0)
        q.push(it);
    }
  }
  return topo;
}
```

$\approx O(N)$

@Aashish Kumar Nayak

Detect a cycle in directed graph using topological sort → BFS

in previous con we used vis, pathvisited and when we were returning then we resetting the pathvisitid array.

But in BFS we can't do that like backtracking

So we use Kahn's Algo

This is a direct cyclic graph

1 — 2
2 — 3
3 — 4, 5
4 — 2
5 → 4

Toposort is only applicable for DAG

lets try to find out the topological sort for this Direct cyclic graph

Kahn's algo
indegree
queue
reduce indegree by 1

So for this toposort will be

$\boxed{1}$

So if Toposort has N elements then it must be DAG

& if ~~si~~ Toposort has less than N element than it must have cycle.

@Aashish Kumar Nayak

Code:- Code is same as Kahn's Algo

we will just ~~tak~~ check size of toposort array in last if size of toposort == N then there is no cycle ~~or~~ and if size is less than V then there is cycle.

```
bool iscycle(int v, vector<int> adj[])
{ int indegree[v] = {0};
  for(int i=0; i<v; i++)
    {  for(auto it: adj[i])
         {  indegree[it]++;
         }
    }
  queue<int> q;
  for(int i=0; i<v; i++)
      {  if(indegree[i] == 0)
           q.push(i);
      }
  }
  int cnt=0;
while(!q.empty())
  {  int node = q.front();
     q.pop();
     cnt++;
  for(auto it: adj[node])
     {  indegree[it]--;
        if(indegree[it]==0)
           q.push(it);
     }
  }
  if(cnt == v)
     return false;
return true;
}
```

T.C. - O(V+E)

S.C. - O(N)

@Aashish Kumar Nayak

Course schedule - I & II

pre requisite task

[1, 0]
[2, 1]
[3, 2]

3 2 1 0 Yes

[1, 2]
[4, 3]
[3, 4]
[4, 1]

No

This is happing because cycle is present.

We can use topological sort.

$u \rightarrow v$ (u, v)

u must have before v

Topo sort

Direct & Acyclic

Alien Dictionary | Topological sort

Alien

baa
abcd
abca
cab
cad

Normal a b c d e f g h - - -

abca
abcd
baa
cab
cad

a comes before b

b comes before c

find out ~~the order~~ " find out the alien order?

~~b a c~~ [b d a c] Alien order

*** This question says something before something so use Topological sort.

i = 0

baa
abcd
abca
cab
cad

Figure out where char is not equal and then make DG according to that

k = 5

a b c a c
0 1 2 3 4 5

[b d a c] — Toposort return ans

$s_1 = arr[i]$;

$s_2 = arr[i+1]$;

compare s_1 & s_2

if we got unequal char then make Directed graph

then after completing the graph. We will do toposort then return the toposort.

@Aashish Kumar Nayak

* what if order is not possible. like abcd $-s_1$
abc $-s_2$

if the largest string is before smallest string and every character of small string is matched

then its wrong dictionary.

* And also when there is cyclic dependency

ex:- a b c
b a f
a d e

wrong dictionary $a \to b$

$a < b$.

$\times$ $b < a$

not possible

```
String findOrder( string dict[], int N, int K)
{   vector<int> adj[K];
    for( int i=0; i<N-1; i++)
    {   string s1 = dict[i];
        string s2 = dict[i+1];
        ~~for~~ int len = min(s1.size(), s2.size());
        for( int ptr=0; ptr<len; ptr++)
        {   if( s1[ptr] != s2[ptr] )
            {   ~~adj[s1[ptr]].push_back(s2[ptr]);~~
                ~~break;~~
                adj[s1[ptr]-'a'].push_back(s2[ptr]-'a');
                break;
            }
        }
    }

    vector<int> topo = toposort( K, adj);
    string ans = "";
    for( auto it : topo)
    {   ans = ans + char( it + 'a');
    }
    return ans;
}
```

no. of string

total char.

@Aashish Kumar Nayak

```
vector<int> toposort( int V, vector <int> adj [])
{   int indegree [V] ={0};
    for( int i=0; i<V; i++)
    {  for(auto it : adj[i])
       {     indegree[it]++;
       }
    }

```
void toposort(int node, vector<pair<int,int>> adj[],
int vis[], stack<int> & st)
{
    vis[node] = 1;
    for(auto it: adj[node])
    {
        int v = it.first;
        if(!vis[v])
        {
            toposort(v, adj, vis, st);
        }
    }
    st.push(node);
}
```

T.C. $\approx O(N+M)$

S.C. $\approx O(N)$

intution:

Finding the shortest path to a vertex is easy if you already know the shortest path of all the vertices that can precede it. Finding the longest path to a vertex in DAG is easy if you already know the longest path to all the vertices that can precede it.

Processing the vertices in topological order ensures that by the time you get to a vertex, you have already processed all the vertices that can precede it.

Dijkstra's algorithm is necessary for graphs that can contain cycles, because they can't be topological sorted.

@Aashish Kumar Nayak

Shortest path in undirected graph having unit distance :-

①

This soln will not work on leetcode (T.L.E) but it is fine and acceptable in interview.

T.C. It will vary with different examples. it is next to impossible ☺ to find T.C. of this code.

@Aashish Kumar Nayak

~~Word ladder~~ : II (~~optimised~~ approach)

only for CP

DIJKSTRA'S ALGORITHM using priority queue

we always wanted minimum distance at 1st.

Reason for using Priority-Queue

Dijkstra's Algorithm → shortest path

Adj list

node, weight

0 → {1, 4}, {2, 4}

1 → {0, 4} {2, 2}

2 → {0, 4}, {1, 2}, {3, 3}, {4, 1} {5, 6}

3 → {2, 3}, {5, 2}

4 → {2, 1}, {5, 3}

5 → {2, 6}, {3, 2}, {4, 3}

0 → 0 d=0

→ 1 d=4

2 d=4

3

There is two methods in Dijkstra's Algo

1. priority queue take less time
2. Set — fastest
3. queue — ✗ Take much time

min heap

{dist, node}

dist = 4 node = 2

node	5	0	1	3	4
dist	4+6 =10	4+4 =8	4+2 =6	3+5 =7	1+4 =5

dist	0	4	4	7	5	10
	0	1	2	3	4	5

d = 0 node = 0

node: 1, 2

distance = 0+4, 0+4

node = 4 dist = 5

node: 2, 5

dist = 5+4 =9, 5+3 =8

d = 4 node = 1

node: 0, 2, 5

dist: 4+4 =8, 4+2 =6

dist = 7 node = 3

node: 2, 5

dist: 7+3 =10, 7+2 =9

dist = 8 node = 5

node: 2, 3, 4

dist: 14, 10, 17

dist = 10 node = 5

2, 5, 4

16, 12, 13

@Aashish Kumar Nayak

return dist; Ans

Neo code :-

@Ashish kumar Nayak

```
~~vector<int> dijkstra(int v, vector<vector<pair<int,int>>~~
vector<int> dijkstra( int v , vector<vector<int>> adj[ ], int S)
{ priority_queue<pair<int,int>, vector<pair<int,int>>,
    greater<pair<int,int>> pq;

  vector<int> dist(v);
  for(int i=0; i<v; i++)
        dist[i]=1e9;
  dist[S] = 0;
  pq.push({0,S});
  while (!pq.empty())
   { int dis = pq.top().first;
   int node = pq.top().second;
   pq.pop();
   for(auto it : adj[node])
    { int edgeweight = it[1];
      int adjNode = it[0];
    if ( dis + edgeweight < dist[adjNode])
    { dist[adjNode] = dis + edgeweight;
      pq.push({dist[adjNode], adjNode});
    }
   }
  }
  return dist;
}
```

T.C. $E \log V$

edges nodes

* Dijkstra does not works in → negative weight
→ negative cycle

(0) —-2— (1)

dist | ~~0~~ | ~~-2~~ |
-2 0 1

-4

Infinite loop

Dijkstra's is applicable for the weight.

Dijkstra's Algorithm (using set) :-

we always wanted minimum distance at first, so we used priority_queue in previous approach.

Set :- set stores unique value and smallest value at the top (ascending order)

Set

{dist, node}

node = 0 —+4→ node = 1, d = 4

node = 0 —+4→ node = 2, d = 4

node = 4, dist = 4 —+4→ node = 0, d = 8

node = 4, dist = 4 —+2→ node = 2, d = 6

node = 4, d = 5 —+1→ node = 2, d = 6

node = 4, d = 5 —+3→ node = 5, d = 8

dist[] =

0	~~4~~	~~4~~	~~7~~	~~5~~	~~10~~
0	1	2	3	4	5

st.erase(); — Logn

But we are saving iterations

@Aashish Kumar Nayak

Code :-

```
vector<int> dijkstra's (int V, vector<vector<int>> adj[], int s)
{ set<pair<int, int>> st;
  vector<int> dist (V, 1e9);
    st.insert({0, s});
    dist[s] = 0;
  while (!st.empty())
    {  auto it = *(st.begin());
       int node = it.second;
       int dis = it.first;
       st.erase(it);
       for (auto it : adj[node])
         {
           int adjNode = it[0];
           int edgw = it[1];
         if(dis + edgw < dist[adjNode])
           {
             if (dist[adjNode] != 1e9)
               st.erase({dist[adjNode], adjNode});
             dist[adjNode] = dis + edgw;
             st.insert({dist[adjNode], adjNode});
           }
         }
    }
    return dist;
}
```

@Aashish Kumar Nayak

Dijkstra's Algorithm

Why PQ and not Q, intution, Time Complexity Derivation

TIME complexity **O(E log V)**

dist[]

* if we are using Q it means we are doing Brute force we are traversing all the path.
* in set or priority queue its like we are using greedy algo.

Q will take lot mor time complexity.

@Aashish Kumar Nayak

if we use priority queue we explore minimal-minimal-minimal - - - - - -

T.C. $E \log V$

E → no. of edges, V → no. of nodes

Print shortest path - Dijkstra's Algorithm :

src = 1
dst = 5

8 paths -

	sum
1 - 2 - 5	= 7
1 - 2 - 3 - 5	= 7
1 - 4 - 3 - 5	6 ✓ shortest path

we need to print path

$\boxed{1 - 4 - 3 - 5}$

HINT

remember where I am coming from than backtrack the path

priority-queue

	1	2	3	4	5
parent	1	~~1~~	~~4~~ 3	~~1~~	~~3~~ 2 5
dis[]	~~0~~	~~2~~	~~4~~	~~1~~	~~5~~ ~~7~~

dist = 5

1 → 4 → 3 → 5

5 come from 3

go to 3 and check where did 3 coming from

dist[1] = 0
then stop

or
if node equals to src.
then stop

→ then we will store it in array
→ Reverse the array
→ return the array

Code :-

```
vector<int> shortestPath(int n, int m,
vector<vector<int>> & edges)
{
  vector<pair<int,int>> adj[n+1];
  for (auto it : edges)
    {  adj[it[0]].push_back({it[1], it[2]});
       adj[it[1]].push_back({it[0], it[2]});
    }

  priority_queue<pair<int,int>, vector<pair<int,int>>,
greater<pair<int,int>>> pq;
  vector<int> dist(n+1, 1e9), parent(n+1);
  for(int i=1; i<=n; i++)
    {  parent[i] = i;
  dist[1] = 0;
  pq.push({0, 1});
```

@Aashish Kumar Nayak

```
while(!pq.empty())
{
    auto it : pq.top();
    int node = it.second;
    int dis = ~~it.second~~ it.first;
    pq.pop();

    for(auto it : adj[node])
    {
        int adjNode = it.first;
        int edw = it.second;
        if(dis + edw < dist[adjNode])
        {
            dist[adjNode] = dis + edw;
            pq.push({dist + edw, adjNode});
            parent[adjNode] = node;
        }
    }
}

if(dist[n] == 1e9)
    return -1;
vector<int> path;
int node = n;
while(parent[node] != node)
{
    path.push_back(node);
    node = parent[node];
}
path.push_back(1);
reverse(path.begin(), path.end());
return path;
}
}
```

$\simeq O(N \times M)$

@Aashish Kumar Nayak

Cheapest Flights within K stops :-

src = 0, dest = 3, K = 1

at max we can take K stops

let's see why simple Dijkstra's will fail

cost
dist[]

0	1	2	3	4
0	~~5~~ 4	~~9~~	~~2~~	~~5~~

src = 0
dest = 2
K = 2

stops = 1
cost = 5

cost = 2
stops = 1

cost = 4
stops = 2

pq
{dist, node, stops}

cost = 5

cost = 9
stops = 1

cost = 10

cost = 6
stops = 2

This path has sortest distance but more stops so we can't choose this.

∴ Dijkstra's Algo store everything in terms of distance, but in this question we have to store in terms of stops.

@Aashish Kumar Nayak

dist[]" =

0	1	2	3	4
0	5	7/6	2	6

~~{3, 2, 7}~~
~~{2, 2, 10}~~
~~{2, 4, 6}~~
~~{7, 3, 2}~~
~~{1, 1, 5}~~
{0, 0, 0}

{stops, node, dist}

~~we~~ there no need of priority queue because ~~st~~ stops are increasing constantly.
we can extra O(log N)

Code :

```
int CheapestFlights( int n , vector<vector<int>> & flights,
int src, int dst ,int k)
{ vector<pair<int, int>> adj[n];
for( auto it : flights)
  { adj[ it[0]].push_back( {it[1], it[2]});
  }
queue<pair<int, pair<int, int>>> q;
  q.push({0, {src , 0}});
  vector<int> dist(n, 1e9);
  dist[src] = 0;
```

@Aashish Kumar Nayak

```
while(!q.empty())
  { auto it = q.front();
    q.pop();
  int stops = it.first;
  int node = it.second.first;
  int cost = it.second.second;
  if(stops > K)
    continue;
  for(auto iter : adj[node])
    {  int adjNode = iter.first;
       int edw = iter.second;

       if(cost + edw < dist[adjNode] &&
          stops <= K)
         {  dist[adjNode] = cost + edw;
            q.push({stops + 1, {adjNode, cost + edw}});
         }
    }
  }
  if(dist[dst] == 1e9)
      return -1;
  else
      return dist[dst];
}
```

T.C. $O(E \cancel{\log V})$

But we are not using PQ

so $O(E)$ ✓

S.C. Flight.size().

@Ashish Kumar Nayak

Belman ford Algorith (~~Shor~~ Algorithm for finding shortest path)

Need of Belman ford Algorithm :-

It Helps us to detect negative cycles.

In Dijkstra's we can not calculate distance with -ve weight or -ve cycle.

But in Belman ford Algo we can calculate path with -ve weight or -ve cycle.

This Algo is Applicable for → DG

Ex:-

if we have

then change it to

→ Dijkstra will fail in TLE or infinite loop.

path weight = ~~-1~~ $-2-1+1$
$= -1$

if path weight < 0 it has negative cycle.

Belman ford Algo :-

src = 0

adj list

(u, v, wt)
(3, 2, 6)
(5, 3, 1)
(0, 1, 5)
(1, 5, -3)
(1, 2, -2)
(3, 4, -2)
(2, 4, 3)

This operation for all edges and it will count 1st iteration

⊛ This algo says Relax all the edges N-1 times sequentially

⊛⊛ This is called Relax

```
if( dist[u] + wt < dist[v] ).
    dist[v] = dist[u] + wt
```

@Aashish kumar Nayak

dist

0	1	2	3	4	5
0	~~5~~	~~3~~	~~∞~~	~~6~~	~~2~~

(u, v, wt)

1st iteration

dist[3] + 6 < dist[2] — (3, 2, 6)

dist[5] + 1 < dist[3] — (5, 3, 1)

dist[0] + 5 < dist[1] — (0, 1, 5)

dist[1] + 3 < dist[5] — (1, 5, -3)

dist[1] − 2 < dist[2] — (1, 2, -2)

dist[3] − 2 < dist[4] — (3, 4, -2)

dist[2] + 3 < dist[4] — (2, 4, -3)

dist

0	1	2	3	4	5
0	5	3	3	1	2

2nd iteration

dist[3] + 6 < dist[2] — (3, 2, 6)

dist[5] + 1 < dist[3] — (5, 3, 1)

dist[0] + 5 < dist[1] — (0, 1, 5)

dist[1] − 3 < dist[5] — (1, 5, -3)

dist[1] − 2 < dist[2] — (1, 2, -2)

dist[3] − 2 < dist[4] — (3, 4, -2)

dist[2] + 3 < dist[4] — (2, 4, -3)

3rd iterati

① Why N-1 cycles

② How we detect negative cycle.

→ 0 helps to calculate 1, than 1 helps, 5 ---- so on

∴ there are N nodes

(N-1) iteration

(N-1) edges

Hence (N-1) cycles

@Aashish Kumar Nayak

since, in a graph of N nodes, in worst case, you will take N-1 edges to reach from the first to the last, thereby we iterate for N-1 iteration.

Try drawing a graph which takes more than N-1 edges for any path, it is not possible.

Q How to detect -ve cycle, becaus in every iteration we are decreasing path value

On Nth iteration the relaxation will be done and the distance array get reduced.

We should get our answer till $(N-1)^{th}$ iteration but if it is still reducing in Nth iteration it means there is a negative cycle.

Code:

```
vector<int> bellman_ford(int v, vector<vector<int>> &edges,
int s)
{ ~~dist[s] = 0;~~ vector<int> dist(v, 1e8); dist[s] = 0;
  for(int i = 0; i < v-1; i++)
  { for(auto it : edges)
    { int u = it[0];
      int v = it[1];
      int wt = it[2];
      if( dist[u] != 1e8 && dist[u] + wt < dist[v])
      { dist[v] = dist[u] + wt;
      }
    }
  }
  // Nth iteration to check negative cycle
  for(auto it : edges)
  { int u = it[0]; int v = it[1]; int wt = it[2];
    if(dist[u] != 1e8 && dist[u] + wt < dist[v])
    { return {-1};
    }
  }
  return dist;
}
```

T.C. ≈ O(V×E)
nodes edges

@Aashish Kumar Nayak

Floyd Warshall Algorithm (Algorithm for shortest path)

This is very-very different from Dijkstra & Bellman ford.

in these two previous Algo src source point is 1.

But in floyd warshall algo there is multiple source point.

we have to find shortest distance of all node from each node.

This is also known as multi source shortest path algorithm

Note: via every Nodes/Vertex.

0 1

$0 \to 1 = 6$

$(0 \to 2) + (2 \to 1) = 5$

2 3

$(0 \to 3) + (3 \to 1) = 5$

4 1

$(0 \to 4) + (4 \to 1) = 4$

3 1

$min(d[i][k] + d[k][j])$

$$\begin{array}{c|cccc} & 0 & 1 & 2 & 3 \\ \hline 0 & 0 & 2 & \alpha & \alpha \\ 1 & 1 & 0 & 3 & \alpha \\ 2 & \alpha & \alpha & 0 & \alpha \\ 3 & 3 & 5 & 4 & 0 \end{array}$$

cost

UG → DG

$0 \to 5$

$0 \to 5$

$0 \leftarrow 5$

$[0][1] = 0 \to 0 + 0 \to 1$

$[0][2] = [0][0] + [0][2]$

$[1][2] = [1][0] + [0][2]$

$1 + \alpha$

@Ashish Kumar Nayak

This algorithm is not much intuitive as the other ones. It is more of a brute force, where all combination of paths have been tried to get the shortest paths.

Nothing to be panic much on the intution, it is a simple brute on all paths. Focus on the three for loops.

(*) How to detect -ve cycle.

$-2 + 2 - 3$

cost $= -3$

if the costing of any node cost[i][i] < 0 (node to node) it means there will have negative cycle.

Code :-

```
void shortest_distance (vector<vector<int>> &matrix)
{ int n = matrix.size();
    for(int i = 0; i<n; i++)
      { for(int j=0; j<n; j++)
          {  if(matrix[i][j] == -1)
               { matrix[i][j] = 1e9;
               }
             if(i==1)
               { matrix[i][j] = 0;
               }
          }
      }

    for(int k = 0; k<n; k++)
      { for(int i=0; i<n; i++)
          { for(int j = 0; j<n; j++)
              { matrix[i][j] = min(matrix[i][j], matrix[i][k] + matrix[k][j]);
```

T.C. - $O(N^3)$

S.C. $O(N^2)$ matrix

//for negative cycle

```
    for(int i=0; i<n; i++)
      { if(matrix[i][i] < 0)
          { //we can return or print something.
          }
    for(int i=0; i<n; i++)
      { for(int j=0; j<n; j++)
          { if(matrix[i][j] == 1e9) { matrix[i][j] = -1; }
            ~~if(i==j) { matrix~~
          }
    }
```

@Aashish Kumar Nayak

City with the smallest no. of Neighbours at a threshold distance

threshold = 4

city

0 → 1, 2 — lowest no. of neighbour

1 → 0, 2, 3

2 → 0, 1, 3

3 → 1, 2

0, 3

largest one is 3

∴ Ans = 3

	0	1	2	3
0	0	3	4	5
1	3	0	1	2
2	4	1	0	1
3	5	2	1	0

cnt = 0

cntmax = 5 ∵ we have 4 cities

city = -1

cnt max = 3

for 0 including itself

cnt = ~~1~~ 2 3, so cnt = 3

for 1

cnt = 1 2 ~~3~~ 4

cntmax = min(cnt, cntmax)

for 2

cnt = 1 2 3 4 = cnt = 4

for 3

cnt = 1 2 3 cnt = 3

cntmax = min(cnt, cntmax)

take largest one.

@Aashish Kumar Nayak

```
int findCity(int n, int m, vector<vector<int>>& edges,
int distanceThreshold)
{ vector<vector<int>> dist(n, vector<int> (n, INT_MAX));
  for (auto it: edges)
    {   dist[it[0]][it[1]] = it[2];
        dist[it[1]][it[0]] = it[2];
    }
  for(int i=0; i<n; i++)
    { dist[i][i] = 0; }
  for( int k=0; k<n; k++)
    { for (int i=0; i<n; i++)
        { for(int j=0; j<n; j++)
            { if(dist[i][k] == INT_MAX || dist[k][j] == INT_MAX)
                continue;
              dist[i][j] = min(dist[i][j], dist[i][k] + dist[k][j]);
            }
        }
    }
  int cntCity = n;
  int cityNo = -1;
  for(int city = 0; city < n; city ++)
    {   int cnt = 0;
        for(int adjCity = 0; adjCity < n; adjCity ++)
        { if( dist[city][adjCity] <= distanceThreshold)
            cnt ++;
        }
        if(cnt <= cntCity)
        {   cntCity = cnt;
            cityNo = city;
        }
    }
  return cityNo;
}
```

@Aashish Kumar Nayak

Minimum Spanning Tree (MST) :-

N-nodes (5)
M - Edges (6)

A tree in which ~~have~~ have N nodes & N-1 edges & all nodes are reachable from each other.

For this graph

Sum = 16

sum = 20

(MST) Both are spanning tree but jst one is Minimum spaning tree.

For finding MST we have
(i) Prim's Algorith
(ii) Kruskal's Algorith
→ Disjoint set

spanning Trees are :-

sum = 17

@Aashish Kumar Nayak

Prim's Algorithm :-

It helps to find MST (Minimum spanning Tree).

sum = 16

vis[]

0	1	2	3	4
1 ~~0~~	1 ~~0~~	1 ~~0~~	~~0~~ 1	~~0~~ 1

(~~2, 3~~)
(1, 4, 3)
~~(2, 3, 2)~~
~~(2, 4, 2)~~
~~(1, 1, 2)~~
~~(1, 2, 0)~~
~~(2, 1, 0)~~
~~(0, 0, -1)~~

(wt, node, parent)
Min-heap

least wt always

node parent (-1) it means its a 1st node so dont add in MST

look at adjacent of node = 0

sum = ~~0~~ 2

MST → [(0,2) (1,2) (2,3) (3,4)]

@Aashish Kumar Nayak

Code :

```
int spanningTree( int V, vector<vector<int>> adj[])
{ priority_queue<pair<int,int>, vector<pair<int,int>>, greater<int,int>> pq;

vector<int> vis(V,0);

pq.push({0,0});
int sum=0;
while(!pq.empty())
{ auto it = pq.top();
  pq.pop();
  int node = it.second;
  int wt = it.first;
  if(vis[node]==1)
    continue;
  vis[node]=1;
  sum += wt;
  for(auto it : adj[node])
    { int adjNode = it[0];
      int edw = it[1];
      if(!vis[adjNode])
        { pq.push({edw, adjNode});
        }
    }
}
return sum;
}
```

T.C - $O(E \log E)$

@Aashish Kumar Nayak

Disjoint Set Data structure :

important for Online Assessments way.

@Aashish Kumar Nayak

1 & 5 are connected or not?

→ No (use BFS/DFS Traversal to find)
takes O(N+E)
i.e. Brute force

But disjoint set. will do this same on constant time.

It gives

find parent()

union() → rank
→ size

(1,2) (1,2) this function will connect ① & ②

(2,3)
(4,5)
(6,7)

(5,6)
(3,7)

graph is changing and we can find parent or union or is two nodes are ~~cum-part~~ connected or not at any stage.

Dynamic

union() → rank
→ size

we can implement union in two ways rank and size.

① union() by rank

rank array

0	0	0	0	0	0	0
1	2	3	4	5	6	7

parent

1	2	3	4	5	6	7
1	2	3	4	5	6	7

union(u,v)

1. find ultimate parent of u & v, pu, pv
2. find rank of ultimate parents
3. connect smaller rank to larger rank always.

rank	1	2	3	4	5	6	7
	1	0	0	2	0	0	0

parents	1	2	3	4	5	6	7
	1	1	1	4	4	4	6

does 1 & 7 belong to same component

Ans :- No., we will check parents of both 1 & 7

∵ they both are different

Both should have equal ultimate parent.

like

4 is ultimate parent of 8 & 7

Path compression

we will store ultimate parent of each node.

But this side is still same so it can't be reduced

* Actually it is called rank.

not height

@Aashish Kumar Nayak

why connected ~~to~~ smaller to larger

code:-

```
class DisjointSet.
{ vector<int> rank, parent, size;
public:
    DisJointSet(int n)
    {
      rank.resize(n+1, 0);
      parent.resize(n+1, 0); size.resize(n+1);
      for(int i=0; i<=n; i++)
        { parent[i] = i;
          size[i] = 1;
        }
    }
    int findUpar(int node)
    {   if(node == parent[node])
            return node;
        return parent[node] = findUpar(parent[node]);
    }
    void unionByRank(int u, int v)
    {   int ulp_u = findUpar(u);
        int ulp_v = findUPar(v);
        ~~if(rank[ulp_v~~
        if(ulp_u == ulp_v)
            return;
        if( rank[ulp_u] < rank[ulp_v])
            { parent[ulp_u] = ulp_v;
    }
```

@Aashish Kumar Nayak

```
else if( rank[ulp_v] < rank[ulp_u])
        {
            parent[ulp_v] = ulp_u;
        }
    else {
            parent[ulp_v] = ulp_u;
            rank[ulp_u]++;
        }
    }
};

int main()
{
    DisjointSet ds1(7), ds2(8);
        ds.unionByRank(1,2);
        ds.unionByRank(2,3);
        //          (4,5);
        //          (6,7);
        //          (5,6);
    if(ds.findUPar(3) == ds.findUPar(7))

    // ds.unionBySize(3,7);  > dont use Both simultaneously.
    if(ds.findUPar(3) == ds.findUPar(7))
        {
            cout<<"same\n";
        }
    else    cout<<"Not same\n";
    return 0;
}
```

@Aashish Kumar Nayak

```
void unionBysize(int u, int v)
{
    int ulp_u = findUpar(u);
    int ulp_v = findUpar(v);
    if(ulp_u == ulp_v)
        return;

    if(rank[ulp_u] < rank[ulp_v])
        {
            parent[ulp_u] = ulp_v;
    else if (rank[ulp_v] < rank[ulp_u])
        {
            parent[ulp_v] = ulp_u;
        }
    else {
            parent[ulp_v] = ulp_u;
            size[ulp_u] += size[ulp_v];
        }
}
```

Account Merge - DSU

["John", "J1@gmail.com", "J2@com", "J3@com", "J5@com"] — 0
["John", "J4@com"] — 1
["raj", "r1@com", "r2@com", "r3@com"] — 2
["John", "J1@com", "J5@com"] — 3
["raj", "r2@com", "r3@com"] — 4
["many", "M1@com"] — 5

We are merging and disjoint data structure that helps us to merging

J1@com → 0
J2@com → 0
J3@com → 0
J4@com → 1
r1@com → 2
r2@com → 2
J5@com → 3
r3@com → 4
M1@com → 5

When we are traversing in 3 index we saw "J1@com" but it is already a part of index 0 so all rest account of index 3 we will merge at index 0.
And so on.

0 → J1@com, J2@com, J3@com, J5@com
1 → J4@com
2 → r1@com, r2@com
3 →
4 →
5 → M1@com

@Aashish Kumar Nayak

@Ashish Kumar Nayak

Code:-

```
class DisjointSet
{
  ==
}

Vector<vector<string>> mergeDetails(vector<vector<string>> & details)
{
  int n = details.size();
  unordered_map<string, int> mapMailNode;
  for(int i=0; i<n; i++)
  {
    for(int j=1; j<details[i][j];
      if(mapMailNode.find(mail) == mapMailNode.end())
      {
        mapMailNode[mail] = i;
      }
      else
      {
        ds.unionBysize(i, mapMailNode[mail]);
      }
  }
  }

  vector<string> mergeMail[n];
  for(auto it : mapMailNode)
  {
    string mail = it.first;
    int node = ds.findUPar(it.second);
    mergedMail[node].push_back(mail);
  }

  vector<vector<string>> ans;
  for(int i=0; i<n; i++)
  {
    if(mergedMail[i].size() == 0) continue;
    sort(mergedMail[i].begin(), ~~==0~~ mergedmail[i].end());
    vector<string> temp;
    temp.push_back(details[i][0]);
    for(auto it: mergedMail[i])
    {
      temp.push_back(it);
    }
    ans.push_back(temp);
  }
  return ans;
}

Making ~~Connect~~ a Large Island - DSU

size = 6 + 6 + 7 + 1
= 20

size = 10 + 1
= 11

we for using Disjoint set we have to convert an indexes into a single no. so that we can map it and use.

formula = (row * m) + col

```
class DisjointSet {
    ==
    ==
};

class solution {
public:
int maxConnection (vector<vector<int>> & grid)
{ int n=grid.size();
  DisjointSet ds(n*n);
  for(int row=0; row<n; row++)
  { for( int col=0; col<n ; col++)
    { if(grid[i][j] == 0)
        continue;
      int dr[] = {-1, 0, 1, 0};
      int dc[] = {0, -1, 0, 1};
```

@Ashish Kumar Nayak

```
for(int ind = 0; ind<4; ind++)
    { int newr = row + dr[ind];
    int newc = col + dc[ind];

if( isvalid(newr, newc, n) && grid[newr][newc] ==1)
{ int nodeNo = row*n + col;
    int adjNodeno = newr*n + newc;
    ds.unionBysize( nodeNo, adjNodeNo);

    } }
} }
    int mx = 0;
for(int row=0; row<n; row++)
    { for(int col=0; col<n; col++)
        { if(grid[row][col] ==1
            { continue;
        int dr = {-1, 0, 1, 0};
        int dc = {0, -1, 0, 1};
        set<int> components;
        for(int ind=0; ind<4; ind++)
            { int newr = row + dr[ind];
            int newc = col + dc[ind];

            if( isvalid(newr, newc, n)) && grid[newr][newc] ==1)
            { int nodeNo = row * n + col;
            int adjNodeNo = newr*n + newc;
            ds.unionBy size(nodeNo, adjNodeNo);

if( isvalid(newr, newc, n)){
    if(grid[newr][newc] ==1) {
    components.insert(ds.findupar(newr*n + newc));
    } }
    int sizetotal = 0;
for(auto it : components)
    { sizetotal += ds.size[it];
    }
    Mx = max(Mx, sizetotal);
} }
```

@Aashish Kumar Nayak

Ashish Kumar Nayak

```
for( int cellNO=0; cellNo < n*m ; cellNO ++)
{
    Mx = Max(Mx, ds.size[ds.findupar(cellNo)]).
}
return mx;
}
```

$\boxed{T.C.\ O(N^2)}$

Most Stones Removed with same row or column

ans = 4

ans = 3

Remove 1 element in each component

$= (4-1) + (2-1)$
$= 3+1$
$= 4$

$= (1-1) + (1-1) + (4-1)$
$= 0 + 0 + 3$
$= 3$

if there are n stones

C_1	C_2	C_3	C_4
x_1 stones	x_2 stones	x_3 stones	x_4 stones

$x_1 + x_2 + x_3 + \dots = n$ stones

stones are removed $(x_1-1) + (x_2-1) + (x_3-1) + \dots =$

$(x_1 + x_2 + x_3 + \dots) - (1 + 1 + 1 \dots)$

$\boxed{\text{ans} = n - \text{no. of components.}}$ n = no. of stones

Here we are connecting stones to make node.
so we use disjoint set data structure.

we will treat row as a node

if there is stone in a row we will say it belongs to ①

nodes is DS

nodes on DS

2 connected components

for all the stone there is 2 ultimate parents

ans = 6 − 2 = 4 Ans

Code:

we just need the nodes in DISJOINT set which are involved in having a stone.
so we store the rows and columns in map as they will have stones. And we just need to count them once for ultimate parents.

@Aashish Kumar Nayak

Code :-

```
class DisjointSet {
    int(mo
    }
int maxRemove(vector<vector<int>> & stones, int n)
{   int maxRow = 0;
    int maxcol = 0;
    for (auto it : stones)
        { maxRow = max(maxRow, it[0]);
          maxcol = max(maxcol, it[1]);
        }
    DisjointSet ds (maxRow + maxcol + 1);
    unordered_map<int, int> stoneNodes;
    for (auto it : stones)
        { int noderow = it[0];
          int nodecol = it[1] + maxRow + 1;
          ds.unionBySize(noderow, nodecol);
          stoneNodes[noderow] = 1;
          stoneNodes[node col] = 1;
        }
    int cnt = 0;
    for(auto it : stonenodes)
        { if(ds.findupar(it.first) == it.first)
          {
            cnt++;
          }
        }
    return n - cnt;
}
}
```

@Ashish Kumar Nayak

Strongly connected components (SCC) :-

only valid for DG (Directed graph) (Kosaraju's Algorithm)

in this component every pair is reachable

0 2
2 0
1 2
2 1
1 0
0 1

Strong connected component

0 1 2 | 3 | 4 5 6 | 7

4 Strongly connected component

- Sort all the edges according to finishing time.
- Reverse the graph
- Do a dfs.

top →

        dfs3(node, vis, adjT);
      }
    }
    return scc;
}
```

@Aashish Kumar Nayak

Bridges in Graph :-

Any edge on whose removal the graph is broken down into two or more components.

4 – 5
5 – 6
10 – 8

dis[] → DFS time insert on
low[] → Min lowest time insertion of all adjacent nodes apart from parent.

DFS(8)
⇅
DFS(9)

if I can reach you then it is not a bridge.

@ Aashish Kumar Nayak

Code :-

```
int timer = 1;
void dfs( int node, int parent, vector<int> &vis, vector<int> adj[],
int tin[], int low[], vector<vector<int>> )
{
    vis[node] = 1;
    tin[node] = low[node] = timer;
    time++;
    for(auto it: adj[node])
    {
        if(it == parent)
            continue;
        if(vis[it] == 0)
        {
            dfs(it, node, vis, adj, tin, low);
            low[node] = min(low[node], low[it]);
            if(low[it] > tin[node])
            {
                bridges.push_back({it, node});
            }
        }
        else
        {
            low[node] = min(low[node], low[it]);
        }
    }
}
vector<vector<int>> criticalConnections( int n, vector<vector<int>>&
connections) { vector<int> adj[n];
    for(auto it: connections)
    {
        adj[it[0]].push_back(it[1]);
        adj[it[1]].push_back(it[0]);
    }
    vector<int> vis(n,0);
    int tin[n], low[n];
    vector<vector<int>> bridges;
    dfs(0,-1, vis, adj, tin, low, bridges);
    return bridges;
}
```

T.C $\simeq O(V+2E)$

@Aashish Kumar Nayak

Articulation point :-

Nodes on whose removal the graph breaks into multiple components.

Articulation point

Time of insertion Tin[] → store the time of insertion during the BFS.

low low[] → min of all adjacent nodes apart from the parent & visited nodes.

if (low[it] >= tm[node] && parent != -1)

dfs(2) → 3
dfs(3) → 1 it can reach to 3.

1 component 3 component.

component should be ≥ 2

@Ashish Kumar Nayak

Code :-

```
int timer=0;
